Chapter 1

PROPS

1.1 Introduction

This is the technical documentation for PROPS, generated from the source code by Doxygen. For a more didactic and general introduction, see the [PROPS main page](#).

1.2 Installation

If all the dependencies are installed (Python 2.6, IT++, SWIG, numpy), typing 'make' or 'make python' should build PROPS and its Python wrapper code. Typing 'make test' should build all the object files and C++ tests. Typing 'make dist' will build a tarball suitable for distribution. Typing 'python test.py' will run a series of unit tests.

1.3 Overview

1.4 Libraries

[IT++](#) is employed for linear algebra and matrix manipulation. In order to efficiently construct numpy matrices out of IT++ matrices, it helps to know how IT++ stores matrices internally. There does not appear to be clear documentation on this, but PROPS assumes a dense column-major format which is apparently correct.

[SWIG](#) is used to generate python wrappers for the C++ code.

[numpy](#) is used in all Python code for matrix manipulation. Matrices are transferred from IT++ to numpy with the help of SWIG and numpy's C interface.

1.5 Coding Style

The basic coding style is taken from the [Google C++ style guide](#). In particular, operator overloading is used only where it is obvious what the operators should do, and constructors are only used where there is an obvious choice of initialization parameters; appropriately named static methods are used in other cases. Exceptions are used to signal errors, which automatically become Python exceptions under SWIG.

All code is documented with doxygen. Method descriptions are placed in header files (except for static methods). Documentation of static methods is included for work on internals, even though those methods are not accessible from Python.

Chapter 2

Todo List

Member **bluetooth_obs** which one?

test this

Member **char_prod** Check `ch0.size() == ch1.size()`

Member **direct_sum** is there a built-in way to do this?

throw error

Class **FourierFunc** work out how band-limiting will operate

fix **Matrix** workaround

Member **FourierFunc::at(const Partition &part) const** build a hash table for this?

Member **FourierFunc::inverse_fft() const** think about running time of this

Member **FourierFunc::inverse_fourier() const** fix next line for band-limiting

Member **FourierFunc::marginals(Partition part)** precompute intertwining operators

what if not all the dominating partitions are being kept?

Member **FourierFunc::shift(const Permutation &p0, const Permutation &p1) const** test right multiplication

fix this for band-limiting

Member **FourierFunc::zero(std::vector< Partition > ind_parts)** do this with band-limiting instead

provide a way to construct an uninitialized **FourierFunc**

Class **Func** add min, max

Member **Func::convolve(const Func &other)** check dimensions

need a real test of this

Member **Func::fft() const** list running time

disallow 0-element **FourierFunc** construction

Member **Func::fourier() const** list running time

Member `Func::join(Func *d0, Func *d1)` want arbitrary indices for d0, d1

Member `Func::operator*(const Func &other)` check dimensions

Member `Func::restrict_to(int i) const` more general restriction?

Member `gz_irrep_adj_swap_eles` Currently this is Theta(irrep dimension), which does not take advantage of sparseness. Reimplement with map for Theta(lg d) or with hash_map for Theta(1)

Member `intertwine` check size consistency

Member `kostka` should we check here that the Kostka number is nonzero?

Member `Matrix::Matrix(int r, int c)` Fix encapsulation

Member `Matrix::operator+=(const Matrix &m)` check dimensions

Member `mix_pair` Check i, j, p

Member `mix_subset` check $k \leq n$
check that subset makes sense

Member `mult_irrep` right multiplication in wrong order
test this for identity

Member `mult_irrep_left` make sure above is true

Member `multitrack_obs` test this

Member `Partition::minus() const` what should this be called?
check that this is not a partition of 1

Member `Partition::operator()(int i) const` error checking

Member `Partition::Partition(int p, int *parts)` have the constructor sort _parts

Member `Permutation::cont_cycle(int n, int i, int j)` check $j \geq i$

Member `Permutation::from_inverse(int n, const int inv_map[])` error checking

Member `Permutation::swap(int n, int i, int j)` Check i, j

Chapter 3

Class Index

3.1 Class List

Here are the classes, structs, unions and interfaces with brief descriptions:

DimensionMismatch	11
FourierFunc (A function on S_n stored as (band-limited) Fourier coefficients)	12
Func (Real-valued explicitly-stored functions on permutations)	15
IndexOutOfBounds	21
InvalidPartition	22
InvalidPermutation	23
Matrix (A basic explicitly-stored matrix)	24
Partition (Partitions of integers represented explicitly)	26
Permutation (Permutations on n elements)	28
PermutationMismatch	31
Tableau ((standard) Young tableau)	32

Chapter 4

File Index

4.1 File List

Here is a list of all documented files with brief descriptions:

dist.cpp (Some functions for constructing distributions on permutations)	33
dist.h (Definition of Func class for (explicit) distributions on permutations)	35
fourier.cpp (Implementation of Fourier-domain functions for the symmetric group)	37
fourier.h (Declaration of Fourier-domain functions for the symmetric group)	40
fourierfunc.cpp (Implementation of FourierFunc class for manipulating band-limited functions on S_n)	42
fourierfunc.h (Declaration of FourierFunc class for band-limited functions on S_n stored as Fourier coefficients)	43
func.cpp (Implementation of explicit real-valued functions on permutations)	44
func.h (Definition of class for real-valued functions on permutations)	45
matrix.cpp (Implementation of Matrix class)	46
matrix.h (Declaration of an explicitly-stored matrix class)	47
models.cpp (Implementation of various Fourier-domain probabilistic models)	48
models.h (Various Fourier-domain models)	49
obs.cpp (Implementation of various observation models)	50
obs.h (Various observation models)	51
partition.cpp (Implementation of partitions and related things)	52
partition.h (Declarations of partitions and related things: tabloids and tableaux)	54
permutation.cpp (Implementation of Permutation class)	56
permutation.h (Definition of Permutation class)	57
props.h (Include all PROPS header files)	58
README.h	??
speedtest.cpp (A simple way of testing the speed of the FFT)	59
util.cpp (Utility functions for props)	60
util.h (Prototypes of utility functions for props)	61

Chapter 5

Class Documentation

5.1 DimensionMismatch Class Reference

Inherits `std::exception`.

Public Member Functions

- `const char * what () const throw ()`

The documentation for this class was generated from the following file:

- [matrix.h](#)

5.2 FourierFunc Class Reference

A function on S_n stored as (band-limited) Fourier coefficients.

```
#include <fourierfunc.h>
```

Public Member Functions

- [Func inverse_fourier](#) () const
Compute the "naive" inverse Fourier transform.
- [Func inverse_fft](#) () const
Compute the inverse Fourier transform using Clausen's FFT.
- [FourierFunc shift](#) (const [Permutation](#) &p0, const [Permutation](#) &p1) const
Shift this function in the Fourier domain.
- [Matrix marginals](#) ([Partition](#) part)
Compute the matrix of marginals defined by the tabloids on partition part.
- `std::string` [str](#) () const
A string representation of this function as coefficient matrices.
- [Matrix at](#) (const [Partition](#) &part) const
The matrix of Fourier coefficients at the partition part.
- `void` [set](#) (int i, [Matrix](#) m)
Set the ith stored matrix of coefficients to m.
- `void` [set](#) (const [Partition](#) &part, [Matrix](#) m)
Set the matrix of coefficients at part to m.
- `int` [num_elements](#) () const
Return n where this a function over S_n .
- `std::vector`< [Partition](#) > [ind_parts](#) ()
Return the partitions at which Fourier coefficients are stored.

Static Public Member Functions

- `static` [FourierFunc zero](#) (std::vector< [Partition](#) > ind_parts)
Create a zero function with coefficients stored at ind_parts.
- `static` [FourierFunc zero](#) (int nelements)
Create a full (not band-limited) zero function on S_n .

Friends

- [FourierFunc](#) * [uniform_fourier](#) (int n)
The uniform distribution in the Fourier domain on S_n .

5.2.1 Detailed Description

A function on S_n stored as (band-limited) Fourier coefficients.

Todo

work out how band-limiting will operate
fix [Matrix](#) workaround

5.2.2 Member Function Documentation

5.2.2.1 [Matrix FourierFunc::at \(const Partition & part\) const](#)

The matrix of Fourier coefficients at the partition part.

Todo

build a hash table for this?

5.2.2.2 [Func FourierFunc::inverse_fft \(\) const](#)

Compute the inverse Fourier transform using Clausen's FFT.

Todo

think about running time of this

5.2.2.3 [Func FourierFunc::inverse_fourier \(\) const](#)

Compute the "naive" inverse Fourier transform. This is a direct translation of the definition, i.e., a sum over "matrix dot products", and so operates in $\Theta(n!^2)$. This exists for demonstration; in practice [inverse_fft](#) should be used instead

Todo

fix next line for band-limiting

5.2.2.4 [Matrix FourierFunc::marginals \(Partition part\)](#)

Compute the matrix of marginals defined by the tabloids on partition part.

Todo

precompute intertwining operators
what if not all the dominating partitions are being kept?

5.2.2.5 FourierFunc FourierFunc::shift (const Permutation & p0, const Permutation & p1) const

Shift this function in the Fourier domain. If this is the Fourier transform of f , the result is the Fourier transform of $f(p) = f(p_0^{-1} p p_1)$

Todo

test right multiplication

Todo

fix this for band-limiting

5.2.2.6 FourierFunc FourierFunc::zero (std::vector< Partition > ind_parts) [static]

Create a zero function with coefficients stored at `ind_parts`.

Todo

do this with band-limiting instead
provide a way to construct an uninitialized [FourierFunc](#)

The documentation for this class was generated from the following files:

- [fourierfunc.h](#)
- [fourierfunc.cpp](#)

5.3 Func Class Reference

Real-valued explicitly-stored functions on permutations.

```
#include <func.h>
```

Public Types

- typedef double **val_t**

Public Member Functions

- **Func** (const **Func** &f)
- **Func** & **operator=** (const **Func** &f)
- **Func** & **operator+=** (const **Func** &f)
Add another function to this one.
- std::string **str** ()
A string representation of this function.
- **val_t operator()** (const **Permutation** &sigma) const
The actual mapping $S_n \rightarrow R$.
- **Func** * **operator*** (const **Func** &other)
Pointwise product of functions.
- **Func** * **convolve** (const **Func** &other)
Convolution.
- **Func** * **shift** (const **Permutation** &p0, const **Permutation** &p1)
Compute a shifted function f so that $f(p) = \text{this}(p0^{-1} p p1)$.
- void **set** (const **Permutation** &p, **val_t** v)
Set the val of this function at permutation p .
- **FourierFunc** **fourier** () const
Compute the "naive" Fourier transform.
- **FourierFunc** **fft** () const
Compute the Fourier transform using Clausen's FFT.
- **Func** **restrict_to** (int i) const
- **Func** **embed** (int i) const
- int **num_elements** () const
Return n where this a function over S_n .
- **val_t** **marginalize** (**Partition** part, **Permutation** p0, **Permutation** p1)
Compute the probability that the tabloid (part, p0) maps to the tabloid (part, p1).
- **Matrix** **marginals** (**Partition** part)

Compute a matrix of marginals defined by the tabloids on partition part.

- `val_t ordered` (int i, int j)
Compute the sum of $f(p)$ over permutations p such that $p(i) < p(j)$ (for a distribution, compute $P(p(i) < p(j))$).
- `Matrix orderings` ()
Compute the matrix of order marginals: $orderings() \rightarrow (i,j) = ordered(i,j)$.
- `void normalize` ()
Normalize this distribution; public functions should always maintain normalization.
- `std::pair< Func *, Func * > split` (int n)
Split this distribution into two first-order independent distributions.

Static Public Member Functions

- `static Func zero` (int n)
Construct a new function on S_n that is identically zero.
- `static Func * join` (Func *d0, Func *d1)
Construct the distribution formed by joining $d0$ and $d1$ as first-order independent.

Protected Member Functions

- `Func` (int n)
Construct uninitialized func on S_n .

Protected Attributes

- `val_t * func`
The explicit function: $\{0, \dots, n! - 1\} \rightarrow R$.
- `int nelements`
This is a function over $S_{nelements}$.
- `int funclen`
Number of values stored in func, i.e., nelements!

Static Protected Attributes

- `static const int MAX_PRINT_ELEMENTS = 6`
The maximum number of values displayed by the output of str.

Friends

- `Func * uniform` (int n)
Construct the uniform distribution on S_n .
- `Func * mix_subset` (int n, int k, `Permutation::perm_val_t` *subset)
Construct the k -subset mixing model.
- `Func * mix_pair` (int n, int i, int j, `val_t` p)
Construct the pairwise mixing model.
- `Func * insertion_mix` (int n)
Construct the insertion mixing model.
- `Func * mallows` (`Permutation` p0, double c)
The Mallows model.
- `Func * multitrack_obs` (int n, int k, int *tracks, int *obs, `Func::val_t` p)
The multi-track observation model.
- `Func * singletrack_obs` (int n, int i, int j, `Func::val_t` pi)
The single track observation model.
- `Func * bluetooth_obs` (int n, int k, int *tracks, int *obs, `Func::val_t` pi)
The bluetooth observation model.
- `Func * pair_rank_obs` (int n, int i, int j, `Func::val_t` pi)
The pairwise ranking observation model.

5.3.1 Detailed Description

Real-valued explicitly-stored functions on permutations.

Todo

add min, max

5.3.2 Member Function Documentation

5.3.2.1 `Func * Func::convolve` (const `Func` & *other*)

Convolution.

Todo

check dimensions

Todo

need a real test of this

5.3.2.2 `FourierFunc Func::fft () const`

Compute the Fourier transform using Clausen's FFT.

Todo

list running time

Todo

disallow 0-element `FourierFunc` construction

5.3.2.3 `FourierFunc Func::fourier () const`

Compute the "naive" Fourier transform. This is a direct translation of the definition; it exists only for testing/demonstrating; in practice `fft` should be used instead

Todo

list running time

5.3.2.4 `Func * Func::join (Func * d0, Func * d1) [static]`

Construct the distribution formed by joining `d0` and `d1` as first-order independent.

Todo

want arbitrary indices for `d0`, `d1`

5.3.2.5 `Matrix Func::marginals (Partition part)`

Compute a matrix of marginals defined by the tabloids on partition `part`. The (i,j) entry of the matrix is the probability that tabloid `i` maps to tabloid `j`, where tabloids are enumerated in the order given by `tabloid_list`

5.3.2.6 `Func * Func::operator* (const Func & other)`

Pointwise product of functions.

Todo

check dimensions

5.3.2.7 `Func Func::restrict_to (int i) const`

Todo

more general restriction?

5.3.2.8 pair< Func *, Func * > Func::split (int n)

Split this distribution into two first-order independent distributions. The first distribution will be a mapping over the indices is in the original distribution, and the second over $\{1, \dots, n\} \setminus is$

5.3.3 Friends And Related Function Documentation**5.3.3.1 Func* bluetooth_obs (int n, int k, int * tracks, int * obs, Func::val_tp) [friend]**

The bluetooth observation model.

Todo

which one?
test this

5.3.3.2 Func* mallows (Permutation p0, double c) [friend]

The Mallows model. The distribution defined by $P(p) = \exp(-c * d(p, p0))$ where d is the Kendall's tau distance: the number of adjacent swaps to transform p^{-1} into $p0^{-1}$

5.3.3.3 Func* mix_pair (int n, int i, int j, val_tp) [friend]

Construct the pairwise mixing model.

Todo

Check i, j, p

5.3.3.4 Func* mix_subset (int n, int k, Permutation::perm_val_t * subset) [friend]

Construct the k-subset mixing model.

Todo

check $k \leq n$

Todo

check that subset makes sense

5.3.3.5 Func* multitrack_obs (int n, int k, int * tracks, int * obs, Func::val_tp) [friend]

The multi-track observation model.

Todo

test this

5.3.3.6 `Func* pair_rank_obs (int n, int i, int j, Func::val_t pi) [friend]`

The pairwise ranking observation model. The pairwise ranking model is defined as π_i for permutations p where $p(i) < p(j)$ and $1 - \pi_i$ otherwise

5.3.4 Member Data Documentation

5.3.4.1 `val_t* Func::func [protected]`

The explicit function: $\{0, \dots, n! - 1\} \rightarrow \mathbb{R}$. The indexing used is that defined by [Permutation::index](#)

The documentation for this class was generated from the following files:

- [func.h](#)
- [func.cpp](#)

5.4 IndexOutOfBounds Class Reference

Inherits `std::exception`.

Public Member Functions

- `const char * what () const throw ()`

The documentation for this class was generated from the following file:

- [permutation.h](#)

5.5 InvalidPartition Class Reference

Inherits `std::exception`.

Public Member Functions

- `const char * what () const throw ()`

The documentation for this class was generated from the following file:

- [partition.h](#)

5.6 InvalidPermutation Class Reference

Inherits `std::exception`.

Public Member Functions

- `const char * what () const throw ()`

The documentation for this class was generated from the following file:

- [permutation.h](#)

5.7 Matrix Class Reference

A basic explicitly-stored matrix.

```
#include <matrix.h>
```

Public Types

- typedef double `mat_val_t`
The type used for matrix entries.

Public Member Functions

- `Matrix` (const `Matrix` &m)
- `Matrix` & `operator=` (const `Matrix` &m)
- `Matrix operator*` (mat_val_t s) const
- `Matrix operator+=` (const `Matrix` &m)
- `mat_val_t ele` (int i, int j) const
- `mat_val_t matrix_dot` (const `Matrix` &m) throw (DimensionMismatch)
*Compute the matrix dot product, $\text{trace}(\text{this}^T * m)$.*
- void `set` (int r, int c, mat_val_t val)
Set the (r;c) element to val.
- `Matrix submat` (int r0, int c0, int r, int c) const
- int `num_rows` () const
- int `num_cols` () const
- `mat_val_t trace` () const
The trace of this matrix, i.e., the sum of the diagonal elements.
- std::string `str` () const
- `Matrix` (int r, int c)

Static Public Member Functions

- static `Matrix identity` (int n)
Construct an $n \times n$ identity matrix.
- static `Matrix zero` (int r, int c)
Construct an $r \times c$ zero matrix.
- static `Matrix direct_sum` (std::vector< `Matrix` > ms)

Public Attributes

- [mat_val_t * mat](#)
The matrix stored in row major order.
- [int rows](#)
Number of rows in matrix.
- [int cols](#)
Number of columns in matrix.

5.7.1 Detailed Description

A basic explicitly-stored matrix.

5.7.2 Constructor & Destructor Documentation

5.7.2.1 Matrix::Matrix (int *r*, int *c*)

Todo

Fix encapsulation

Construct an uninitialized $r \times c$ matrix

5.7.3 Member Function Documentation

5.7.3.1 Matrix::mat_val_t Matrix::matrix_dot (const Matrix & *m*) throw (DimensionMismatch)

Compute the matrix dot product, $\text{trace}(\text{this}^T * m)$. Note that this is $\Theta(nm)$ while computing $\text{trace}(\text{this}^T * m)$ explicitly is $O((nm)^2)$

5.7.3.2 Matrix Matrix::operator+= (const Matrix & *m*)

Todo

check dimensions

The documentation for this class was generated from the following files:

- [matrix.h](#)
- [matrix.cpp](#)

5.8 Partition Class Reference

Partitions of integers represented explicitly.

```
#include <partition.h>
```

Public Member Functions

- **Partition** (int p, int *parts) throw (InvalidPartition)
Create a new partition of sum(parts) consisting of p parts.
- **Partition** (const **Partition** &p)
Copy constructor.
- **Partition** & **operator=** (const **Partition** &p)
- int **operator()** (int i) const
Return the size of the ith greatest element of this partition.
- int **num** () const
The number that this partition partitions.
- int **num_parts** () const
The number of parts of this partition.
- int **hook_len** (int i, int j) const
The hook length from the box at component i, position j.
- std::vector< **Partition** > **minus** () const
- **Partition** **decr** (int i) const
Form a new partition by decrementing the ith component of this one.
- **Partition** **subpart** (int start, int end) const
- **Partition** **concat** (const **Partition** &part) const
- bool **operator==** (const **Partition** &p) const
Test two partitions for equality.
- bool **operator!=** (const **Partition** &p) const
Opposite of ==.
- bool **dominates** (const **Partition** &p) const
Return true iff this partition dominates p.
- std::string **str** () const
A string representation of the partition.
- std::string **repr** () const

Static Public Member Functions

- static `std::vector< Partition > list` (int n)
Enumerate partitions in lexicographic order.
- static `std::vector< Partition > list_up_to` (int n, unsigned int size)

5.8.1 Detailed Description

Partitions of integers represented explicitly.

5.8.2 Constructor & Destructor Documentation

5.8.2.1 `Partition::Partition` (int *_p*, int * *_parts*) throw (`InvalidPartition`)

Create a new partition of `sum(parts)` consisting of `p` parts.

Todo

have the constructor sort `_parts`

5.8.3 Member Function Documentation

5.8.3.1 `bool Partition::dominates` (const `Partition & p`) const

Return true iff this partition dominates `p`. Domination is taken in the weak sense, so `p.dominates(p)` returns true

5.8.3.2 `vector< Partition > Partition::minus` () const

Todo

what should this be called?

Todo

check that this is not a partition of 1

5.8.3.3 `int Partition::operator()` (int *i*) const

Return the size of the `i`th greatest element of this partition.

Todo

error checking

The documentation for this class was generated from the following files:

- [partition.h](#)
- [partition.cpp](#)

5.9 Permutation Class Reference

Permutations on n elements.

```
#include <permutation.h>
```

Public Types

- typedef int `perm_val_t`
The type that this permutation maps.

Public Member Functions

- `Permutation` (int n , const `perm_val_t` _map[]) throw (InvalidPermutation)
Construct a permutation given the explicit mapping.
- `Permutation` (const `Permutation` &sigma)
Copy constructor.
- `Permutation` & `operator=` (const `Permutation` &other)
- int `min_cycle_ele` () const
The minimum i that is not mapped to i .
- `perm_val_t` `operator()` (`perm_val_t` i) throw (IndexOutOfBounds)
The result of applying this permutation to i .
- `Permutation of` (const `Permutation` &sigma) const throw (PermutationMismatch)
Composition of permutations, i.e., this o sigma.
- `Permutation inverse` () const
The inverse permutation, $this^{-1}$.
- `Permutation direct_sum` (const `Permutation` &sigma) const
The direct sum of permutations.
- int `index` () const
Implements a bijection from S_n to $\{0, \dots, n! - 1\}$.
- int `num_elements` () const
The number of elements permuted.
- bool `setmapsto` (int k , int *is, int *js)
- std::string `str` ()
Produce a "one line" explicit string representation.
- std::string `repr` ()
- std::vector< `Permutation` > `factor_swaps` ()
Factor this permutation into swaps (transpositions).

- `std::vector< Permutation > factor_adj_swaps ()`
Factor this permutation into adjacent swaps (transpositions of the form $(i,i+1)$).
- `Permutation ()`
For constructing by static methods.

Static Public Member Functions

- static `Permutation identity (int n)`
Construct the identity permutation on n elements.
- static `Permutation swap (int n, int i, int j)`
Construct the transposition of i and j .
- static `Permutation from_inverse (int n, const int inv_map[]) throw (InvalidPermutation)`
Construct a permutation from $\{0, \dots, n-1\}$ permuted, i.e., the inverse mapping.
- static `Permutation cont_cycle (int n, int i, int j)`
- static `Permutation from_index (int n, int i) throw (IndexOutOfBounds)`
Implements a bijection from $\{0, \dots, n! - 1\}$ to S_n .

5.9.1 Detailed Description

Permutations on n elements. A permutation is a mapping from $\{0, \dots, n-1\}$ to $\{0, \dots, n-1\}$, i.e., an element of S_n . Permutations are immutable.

5.9.2 Member Function Documentation

5.9.2.1 `Permutation Permutation::cont_cycle (int n , int i , int j) [static]`

Todo

check $j \geq i$

5.9.2.2 `Permutation Permutation::direct_sum (const Permutation & σ) const`

The direct sum of permutations. If p_0 is in S_n , p_1 is in S_m , the direct sum $p_0 (+) p_1 = p$ is defined so that $p(i) = p_0(i)$ when $i < n$ or $p_1(i - n) + n$ when $i \geq n$

5.9.2.3 `Permutation Permutation::from_index (int n , int i) throw (IndexOutOfBounds) [static]`

Implements a bijection from $\{0, \dots, n! - 1\}$ to S_n . This is the inverse operation from `index`

5.9.2.4 `Permutation::from_inverse (int n, const int inv_map[]) throw (InvalidPermutation) [static]`

Construct a permutation from $\{0, \dots, n-1\}$ permuted, i.e., the inverse mapping.

Todo

error checking

5.9.2.5 `int Permutation::index () const`

Implements a bijection from S_n to $\{0, \dots, n! - 1\}$. This is the inverse operation from `from_index`

5.9.2.6 `int Permutation::min_cycle_ele () const`

The minimum i that is not mapped to i . In other words, the first element of the first cycle comprising this permutation. In particular, if this permutation is $(i, i+1)$, returns i . If this is the identity permutation, returns `num_elements()`.

5.9.2.7 `bool Permutation::setmapsto (int k, int *is, int *js)`

Decide if for every i in is there is some j in js such that $p(i) = j$, i.e, if the set of indices is maps unordered to the values js .

k should be the number of values pointed to by is and js . This function is useful for testing tabloid equivalence.

5.9.2.8 `Permutation Permutation::swap (int n, int i, int j) [static]`

Construct the transposition of i and j .

Todo

Check i, j

The documentation for this class was generated from the following files:

- [permutation.h](#)
- [permutation.cpp](#)

5.10 PermutationMismatch Class Reference

Inherits `std::exception`.

Public Member Functions

- `const char * what () const throw ()`

The documentation for this class was generated from the following file:

- [permutation.h](#)

5.11 Tableau Class Reference

(standard) Young tableau

```
#include <partition.h>
```

Public Member Functions

- [Tableau](#) (const [Tableau](#) &t)
Copy constructor.
- std::string [str](#) () const
This tableau, written explicitly.
- std::pair< int, int > [pos](#) (int i) const
- int [axial_dist](#) (int i, int j) const
The axial distance, or (signed) number of steps required to get from i to j by moving in four adjacent directions.
- [Tableau swap](#) (int i) const
Compute (i, i + 1) o (this tabloid).
- bool [operator==](#) (const [Tableau](#) &t)
Test two tableau for equality.

Static Public Member Functions

- static std::vector< [Tableau](#) > [list](#) (const [Partition](#) &part)
Enumerate all standard tableau for a particular partition.
- static int [count](#) (const [Partition](#) &part)
Count the number of tableau of a particular shape using the hook formula.

5.11.1 Detailed Description

(standard) Young tableau

The documentation for this class was generated from the following files:

- [partition.h](#)
- [partition.cpp](#)

Chapter 6

File Documentation

6.1 dist.cpp File Reference

Some functions for constructing distributions on permutations. `#include "dist.h"`

```
#include "util.h"
```

```
#include <cmath>
```

Functions

- `Func * uniform` (int n)
Construct the uniform distribution on S_n .
- `Func * mix_subset` (int n, int k, `Permutation::perm_val_t *subset`)
Construct the k -subset mixing model.
- `Func * mix_pair` (int n, int i, int j, `Func::val_t p`)
Construct the pairwise mixing model.
- `Func * insertion_mix` (int n)
Construct the insertion mixing model.
- `Func * mallows` (`Permutation p0`, double c)
The Mallows model.

6.1.1 Detailed Description

Some functions for constructing distributions on permutations.

6.1.2 Function Documentation

6.1.2.1 Func* mallows (Permutation $p\theta$, double c)

The Mallows model. The distribution defined by $P(p) = \exp(-c * d(p, p_0))$ where d is the Kendall's tau distance: the number of adjacent swaps to transform p^{-1} into p_0^{-1}

6.1.2.2 Func* mix_pair (int n , int i , int j , Func::val_t p)

Construct the pairwise mixing model.

Todo

Check i, j, p

6.1.2.3 Func* mix_subset (int n , int k , Permutation::perm_val_t * $subset$)

Construct the k-subset mixing model.

Todo

check $k \leq n$

Todo

check that subset makes sense

6.2 dist.h File Reference

Definition of `Func` class for (explicit) distributions on permutations. `#include "func.h"`
`#include "partition.h"`

Functions

- `Func * uniform` (int n)
Construct the uniform distribution on S_n .
- `Func * mix_subset` (int n, int k, `Permutation::perm_val_t *subset`)
Construct the k -subset mixing model.
- `Func * mix_pair` (int n, `Permutation::perm_val_t i`, `Permutation::perm_val_t j`, `Func::val_t p`)
Construct the pairwise mixing model.
- `Func * insertion_mix` (int n)
Construct the insertion mixing model.
- `Func * mallows` (`Permutation p0`, double c)
The Mallows model.

6.2.1 Detailed Description

Definition of `Func` class for (explicit) distributions on permutations.

6.2.2 Function Documentation

6.2.2.1 `Func* mallows (Permutation p0, double c)`

The Mallows model. The distribution defined by $P(p) = \exp(-c * d(p, p0))$ where d is the Kendall's tau distance: the number of adjacent swaps to transform p^{-1} into $p0^{-1}$

6.2.2.2 `Func* mix_pair (int n, Permutation::perm_val_t i, Permutation::perm_val_t j, Func::val_t p)`

Construct the pairwise mixing model.

Todo

Check i, j, p

Todo

Check i, j, p

6.2.2.3 Func* mix_subset (int *n*, int *k*, Permutation::perm_val_t * *subset*)

Construct the k-subset mixing model.

Todo

check $k \leq n$

Todo

check that subset makes sense

Todo

check $k \leq n$

Todo

check that subset makes sense

6.3 `fourier.cpp` File Reference

```
Implementation of Fourier-domain functions for the symmetric group. #include "fourier.h"
#include "util.h"
#include <vector>
#include <cmath>
#include <iostream>
#include <itpp/itbase.h>
```

Defines

- #define **SQ(x)** ((x)*(x))
- #define **Matrix** mat

Functions

- static `vector< pair< int, double > >` [gz_irrep_adj_swap_eles](#) (`vector< Tableau >` tabs, int i, int j)
Find the nonzero elements in row (or column) j of the irrep at (i, i+1) in the gz basis given by the specified tableaux.
- `Matrix` [gz_irrep](#) (`Partition` part, `Permutation` p)
Construct the irreducible representation matrix in the Gel'fand-Tsetlin basis at the given permutation.
- static `Matrix` [mult_irrep](#) (`Partition` part, `Permutation` p, `Matrix` m, bool left_mult)
- `Matrix` [mult_irrep_left](#) (`Partition` part, `Permutation` p, `Matrix` m)
Multiply a matrix by the partition part irrep at the permutation p.
- `Matrix` [mult_irrep_right](#) (`Partition` part, `Permutation` p, `Matrix` m)
Like mult_irrep_left, but perform right multiplication instead.
- `vector< int >` [character](#) (`Partition` part)
The character of the irrep at partition part.
- int [char_prod](#) (`vector< int >` ch0, `vector< int >` ch1)
The inner product of characters of two irreps.
- `Matrix` [marginal_rep](#) (`Partition` part, `Permutation` p)
Compute the the marginal representation of S_n at the permutation p for the partition part.
- `Matrix` [direct_sum](#) (`Matrix` m0, `Matrix` m1)
- `Matrix` [direct_sum](#) (`vector< Matrix >` blocks)
*Compute the direct sum a given vector of matrices */.*
- `Matrix` [multi_direct_sum](#) (`Matrix` m, int n)
Compute the multiple direct sum m (+) ... (+) m (n times).
- `Matrix` [kron_factor_id](#) (`Matrix` p, int d)

- **Matrix normalize_rows** (**Matrix** m)
- static **Matrix intertwine** (**Matrix** X0, **Matrix** X1, **Matrix** Y0, **Matrix** Y1, int z)
Compute part of an orthogonal intertwining operator between two orthogonal representations.
- static **Matrix concat_vertical** (vector< **Matrix** > ms)
Vertically concatenate given vector of matrices.
- **Matrix marg_intertwine** (**Partition** part, vector< **Partition** > dom_parts)
Compute an orthogonal intertwining operator between the matrix of marginals at partition part and the matrices of GZ basis irreps at the partitions dom_parts.

6.3.1 Detailed Description

Implementation of Fourier-domain functions for the symmetric group.

6.3.2 Function Documentation

6.3.2.1 int char_prod (vector< int > ch0, vector< int > ch1)

The inner product of characters of two irreps.

Todo

Check `ch0.size() == ch1.size()`

6.3.2.2 Matrix direct_sum (vector< Matrix > blocks)

Compute the direct sum a given vector of matrices */.

Todo

is there a built-in way to do this?

Todo

throw error

6.3.2.3 static vector<pair<int, double> > gz_irrep_adj_swap_eles (vector< Tableau > tabs, int i, int j) [static]

Find the nonzero elements in row (or column) j of the irrep at (i, i+1) in the gz basis given by the specified tableaux. This function exists to allow efficient "sparse" computation with these irreps

Todo

Currently this is `Theta(irrep dimension)`, which does not take advantage of sparseness. Reimplement with `map` for `Theta(lg d)` or with `hash_map` for `Theta(1)`

6.3.2.4 `static Matrix intertwine (Matrix X0, Matrix X1, Matrix Y0, Matrix Y1, int z)` `[static]`

Compute part of an orthogonal intertwining operator between two orthogonal representations. $X0$ and $X1$ should be elements of a representation that correspond to two different elements that generate S_n (such as a transposition and a complete cycle). $Y0$ and $Y1$ should be elements of a different representation that correspond to the same elements of S_n . z should be the multiplicity of the X representation in the Y representation (the dimension of the Y representation should be at least the dimension of the X representation).

In typical use, X is an irrep, Y is a marginal rep, and z is a Koska number.

The matrix returned has orthonormal rows and forms an intertwining operator when stacked with other such matrices generated from X representations that from a decomposition of the representation Y .

Todo

check size consistency

6.3.2.5 `Matrix marg_intertwine (Partition part, std::vector< Partition > dom_parts)`

Compute an orthogonal intertwining operator between the matrix of marginals at partition `part` and the matrices of GZ basis irreps at the partitions `dom_parts`. The partitions from `dom_parts` are used with multiplicities given by the Kostka numbers; any that do not dominate `part` will not be used. Commonly, `dom_parts` will be all partitions above (and including `part`) in the dominance ordering.

6.3.2.6 `Matrix marginal_rep (Partition part, Permutation p)`

Compute the the marginal representation of S_n at the permutation p for the partition `part`. The (i,j) entry of the resulting matrix is 1 if $p(\text{tabloid}_j) = \text{tabloid}_i$, where tabloids are indexed in the order given by `tabloid_list`, composition means applying the map p to each element of the tabloid, and equality means tabloid equivalence. Note the "swiched" order of indices, which is necessary for the composition order of matrices to follow that of permutations.

6.3.2.7 `static Matrix mult_irrep (Partition part, Permutation p, Matrix m, bool left_mult)` `[static]`

Todo

right multiplication in wrong order

Todo

test this for identity

6.3.2.8 `Matrix mult_irrep_left (Partition part, Permutation p, Matrix m)`

Multiply a matrix by the partition `part` irrep at the permutation p . This function is $\Theta(nd)$, where d is the dimension of the matrix and n is the number of adjacent transposition factors of the irrep

Todo

make sure above is true

6.4 `fourier.h` File Reference

Declaration of Fourier-domain functions for the symmetric group. `#include "partition.h"`

```
#include <vector>
```

```
#include <itpp/itbase.h>
```

Defines

- `#define Matrix itpp::mat`

Functions

- [Matrix](#) `gz_irrep` ([Partition](#) part, [Permutation](#) p)
Construct the irreducible representation matrix in the Gel'fand-Tsetlin basis at the given permutation.
- [Matrix](#) `mult_irrep_left` ([Partition](#) part, [Permutation](#) p, [Matrix](#) m)
Multiply a matrix by the partition part irrep at the permutation p.
- [Matrix](#) `mult_irrep_right` ([Partition](#) part, [Permutation](#) p, [Matrix](#) m)
Like mult_irrep_left, but perform right multiplication instead.
- `std::vector< int >` [character](#) ([Partition](#) part)
The character of the irrep at partition part.
- `int` [char_prod](#) (`std::vector< int >` ch0, `std::vector< int >` ch1)
The inner product of characters of two irreps.
- [Matrix](#) `direct_sum` (`std::vector< Matrix >` ms)
*Compute the direct sum a given vector of matrices */.*
- [Matrix](#) `multi_direct_sum` ([Matrix](#) m, `int` n)
Compute the multiple direct sum m (+) ... (+) m (n times).
- [Matrix](#) `marg_intertwine` ([Partition](#) part, `std::vector< Partition >` dom_parts)
Compute an orthogonal intertwining operator between the matrix of marginals at partition part and the matrices of GZ basis irreps at the partitions dom_parts.
- [Matrix](#) `marginal_rep` ([Partition](#) part, [Permutation](#) p)
Compute the the marginal representation of S_n at the permutation p for the partition part.

6.4.1 Detailed Description

Declaration of Fourier-domain functions for the symmetric group.

6.4.2 Function Documentation

6.4.2.1 `int char_prod (vector< int > ch0, vector< int > ch1)`

The inner product of characters of two irreps.

Todo

Check `ch0.size() == ch1.size()`

6.4.2.2 `Matrix direct_sum (vector< Matrix > blocks)`

Compute the direct sum a given vector of matrices */.

Todo

is there a built-in way to do this?

Todo

throw error

6.4.2.3 `Matrix marg_intertwine (Partition part, std::vector< Partition > dom_parts)`

Compute an orthogonal intertwining operator between the matrix of marginals at partition `part` and the matrices of GZ basis irreps at the partitions `dom_parts`. The partitions from `dom_parts` are used with multiplicities given by the Kostka numbers; any that do not dominate `part` will not be used. Commonly, `dom_parts` will be all partitions above (and including `part`) in the dominance ordering.

6.4.2.4 `Matrix marginal_rep (Partition part, Permutation p)`

Compute the the marginal representation of S_n at the permutation `p` for the partition `part`. The (i,j) entry of the resulting matrix is 1 if $p(\text{tabloid}_j) = \text{tabloid}_i$, where tabloids are indexed in the order given by `tabloid_list`, composition means applying the map `p` to each element of the tabloid, and equality means tabloid equivalence. Note the "swiched" order of indices, which is necessary for the composition order of matrices to follow that of permutations.

6.4.2.5 `Matrix mult_irrep_left (Partition part, Permutation p, Matrix m)`

Multiply a matrix by the partition `part` irrep at the permutation `p`. This function is $\Theta(nd)$, where `d` is the dimension of the matrix and `n` is the number of adjacent transposition factors of the irrep

Todo

make sure above is true

6.5 `fourierfunc.cpp` File Reference

Implementation of [FourierFunc](#) class for manipulating band-limited functions on S_n . `#include <vector>`

```
#include <iostream>
#include <sstream>
#include "fourierfunc.h"
#include "partition.h"
#include "func.h"
#include "util.h"
#include "fourier.h"
```

Defines

- `#define Matrix itpp::mat`

6.5.1 Detailed Description

Implementation of [FourierFunc](#) class for manipulating band-limited functions on S_n .

6.6 `fourierfunc.h` File Reference

Declaration of `FourierFunc` class for band-limited functions on S_n stored as Fourier coefficients.

```
#include "partition.h"
```

```
#include <itpp/itbase.h>
```

Classes

- class `FourierFunc`

A function on S_n stored as (band-limited) Fourier coefficients.

Defines

- #define `Matrix` `itpp::mat`

6.6.1 Detailed Description

Declaration of `FourierFunc` class for band-limited functions on S_n stored as Fourier coefficients.

6.7 func.cpp File Reference

Implementation of explicit real-valued functions on permutations. `#include <sstream>`

```
#include <cstring>
#include <iostream>
#include <assert.h>
#include "func.h"
#include "permutation.h"
#include "partition.h"
#include "fourier.h"
#include "util.h"
#include "fourierfunc.h"
```

Defines

- `#define Matrix itpp::mat`

6.7.1 Detailed Description

Implementation of explicit real-valued functions on permutations.

6.8 func.h File Reference

Definition of class for real-valued functions on permutations. `#include <string>`

```
#include "partition.h"
```

```
#include "permutation.h"
```

```
#include <itpp/itbase.h>
```

Classes

- class [Func](#)
Real-valued explicitly-stored functions on permutations.

Defines

- `#define Matrix itpp::mat`

6.8.1 Detailed Description

Definition of class for real-valued functions on permutations.

6.9 matrix.cpp File Reference

Implementation of [Matrix](#) class. `#include "matrix.h"`

```
#include <cstring>
```

```
#include <sstream>
```

```
#include <iomanip>
```

Defines

- `#define MIN(x, y) (((x) < (y)) ? (x) : (y))`

6.9.1 Detailed Description

Implementation of [Matrix](#) class.

6.10 matrix.h File Reference

Declaration of an explicitly-stored matrix class. `#include <exception>`

```
#include <string>
```

```
#include <vector>
```

```
#include <itpp/itbase.h>
```

Classes

- class [DimensionMismatch](#)
- class [Matrix](#)

A basic explicitly-stored matrix.

Functions

- `itpp::mat` **direct_sum** (`std::vector< itpp::mat >` blocks)

6.10.1 Detailed Description

Declaration of an explicitly-stored matrix class.

6.11 models.cpp File Reference

Implementation of various Fourier-domain probabilistic models. `#include "models.h"`

Defines

- `#define Matrix itpp::mat`

Functions

- `FourierFunc * uniform_fourier (int n)`
The uniform distribution in the Fourier domain on S_n .

6.11.1 Detailed Description

Implementation of various Fourier-domain probabilistic models.

6.12 models.h File Reference

Various Fourier-domain models. `#include "fourierfunc.h"`

Functions

- [FourierFunc * uniform_fourier](#) (int n)
The uniform distribution in the Fourier domain on S_n .

6.12.1 Detailed Description

Various Fourier-domain models.

6.13 obs.cpp File Reference

Implementation of various observation models. `#include "obs.h"`
`#include "util.h"`

Functions

- **Func** * `multitrack_obs` (int n, int k, int *tracks, int *obs, Func::val_t pi)
The multi-track observation model.
- **Func** * `singletrack_obs` (int n, int i, int j, Func::val_t pi)
The single track observation model.
- **Func** * `bluetooth_obs` (int n, int k, int *tracks, int *obs, Func::val_t pi)
The bluetooth observation model.
- **Func** * `pair_rank_obs` (int n, int i, int j, Func::val_t pi)
The pairwise ranking observation model.

6.13.1 Detailed Description

Implementation of various observation models.

6.13.2 Function Documentation

6.13.2.1 Func* bluetooth_obs (int n, int k, int * tracks, int * obs, Func::val_t pi)

The bluetooth observation model.

Todo

which one?
test this

6.13.2.2 Func* multitrack_obs (int n, int k, int * tracks, int * obs, Func::val_t p)

The multi-track observation model.

Todo

test this

6.13.2.3 Func* pair_rank_obs (int n, int i, int j, Func::val_t pi)

The pairwise ranking observation model. The pairwise ranking model is defined as pi for permutations p where $p(i) < p(j)$ and $1 - pi$ otherwise

6.14 obs.h File Reference

Various observation models. `#include "func.h"`

Functions

- `Func * multitrack_obs` (int n, int k, int *tracks, int *obs, Func::val_t p)
The multi-track observation model.
- `Func * singletrack_obs` (int n, int i, int j, Func::val_t pi)
The single track observation model.
- `Func * bluetooth_obs` (int n, int k, int *tracks, int *obs, Func::val_t pi)
The bluetooth observation model.
- `Func * pair_rank_obs` (int n, int i, int j, Func::val_t pi)
The pairwise ranking observation model.

6.14.1 Detailed Description

Various observation models.

6.14.2 Function Documentation

6.14.2.1 `Func* bluetooth_obs` (int n, int k, int * tracks, int * obs, Func::val_t pi)

The bluetooth observation model.

Todo

which one?
test this

6.14.2.2 `Func* multitrack_obs` (int n, int k, int * tracks, int * obs, Func::val_t p)

The multi-track observation model.

Todo

test this

6.14.2.3 `Func* pair_rank_obs` (int n, int i, int j, Func::val_t pi)

The pairwise ranking observation model. The pairwise ranking model is defined as pi for permutations p where $p(i) < p(j)$ and $1 - pi$ otherwise

6.15 partition.cpp File Reference

Implementation of partitions and related things. #include "partition.h"

```
#include "util.h"
#include <cstring>
#include <sstream>
#include <iostream>
#include <assert.h>
```

Defines

- #define **MIN**(x, y) ((x) < (y) ? (x) : (y))

Functions

- bool **tabloid_equal** (const [Partition](#) &part, const [Permutation](#) &p0, const [Permutation](#) &p1)

Determine if two Young's tabloids are equal (as tabloids).
- static vector< vector< int > > **ord_subsets** (vector< int > list, unsigned int n)
- static vector< int > **ord_minus** (vector< int > a, vector< int > b)
- static vector< vector< int > > **make_tabloid_list** (const [Partition](#) &part, vector< int > avail)
- static int * **new_list_from_vector** (vector< int > v)
- vector< [Permutation](#) > **tabloid_list** (const [Partition](#) &part)

List all the (tabloid_equal-distinct) Young's tabloids over a partition.
- static vector< [Partition](#) > **fill_ss_tableau** (const [Partition](#) &part, int n, int right)
- int **kostka** (const [Partition](#) &m_part, const [Partition](#) &i_part)

Calculate the multiplicity of an irrep in a given marginal rep.

6.15.1 Detailed Description

Implementation of partitions and related things.

6.15.2 Function Documentation

6.15.2.1 int kostka (const [Partition](#) & m_part, const [Partition](#) & i_part)

Calculate the multiplicity of an irrep in a given marginal rep. This is the Kostka number, calculated according to Young's rule. m_part is the partition defining the marginal rep, and i_part is the partition defining the irrep

Todo

should we check here that the Kostka number is nonzero?

6.15.2.2 bool tabloid_equal (const Partition & *part*, const Permutation & *p0*, const Permutation & *p1*)

Determine if two Young's tabloids are equal (as tabloids). The tabloids are both over the partition *part*, and defined to contain the elements $p0(0)$, $p0(1)$, ... filled in from left to right, largest component to smallest component

6.15.2.3 vector<Permutation> tabloid_list (const Partition & *part*)

List all the (tabloid_equal-distinct) Young's tabloids over a partition. The tabloids are returned as permutations, as described in tabloid_equal

6.16 partition.h File Reference

Declarations of partitions and related things: tabloids and tableaux. `#include "permutation.h"`
`#include <vector>`

Classes

- class [InvalidPartition](#)
- class [Partition](#)
Partitions of integers represented explicitly.
- class [Tableau](#)
(standard) Young tableau

Functions

- bool [tabloid_equal](#) (const [Partition](#) &part, const [Permutation](#) &p0, const [Permutation](#) &p1)
Determine if two Young's tabloids are equal (as tabloids).
- std::vector< [Permutation](#) > [tabloid_list](#) (const [Partition](#) &part)
List all the (tabloid_equal-distinct) Young's tabloids over a partition.
- int [kostka](#) (const [Partition](#) &m_part, const [Partition](#) &i_part)
Calculate the multiplicity of an irrep in a given marginal rep.

6.16.1 Detailed Description

Declarations of partitions and related things: tabloids and tableaux.

6.16.2 Function Documentation

6.16.2.1 int kostka (const Partition & m_part, const Partition & i_part)

Calculate the multiplicity of an irrep in a given marginal rep. This is the Kostka number, calculated according to Young's rule. `m_part` is the partition defining the marginal rep, and `i_part` is the partition defining the irrep

Todo

should we check here that the Kostka number is nonzero?

6.16.2.2 bool tabloid_equal (const Partition & part, const Permutation & p0, const Permutation & p1)

Determine if two Young's tabloids are equal (as tabloids). The tabloids are both over the partition `part`, and defined to contain the elements `p0(0)`, `p0(1)`, ... filled in from left to right, largest component to smallest component

6.16.2.3 `std::vector<Permutation> tabloid_list (const Partition & part)`

List all the (tabloid_equal-distinct) Young's tabloids over a partition. The tabloids are returned as permutations, as described in tabloid_equal

6.17 permutation.cpp File Reference

Implementation of [Permutation](#) class. `#include <sstream>`

```
#include <iostream>
```

```
#include "permutation.h"
```

```
#include "util.h"
```

Functions

- `int * new_seq (int i, int len)`

Return a newly allocated array of length len that counts from i.

6.17.1 Detailed Description

Implementation of [Permutation](#) class.

6.17.2 Function Documentation

6.17.2.1 `int* new_seq (int i, int len)`

Return a newly allocated array of length len that counts from i. The returned array should be freed with delete.

6.18 permutation.h File Reference

Definition of [Permutation](#) class. `#include <string>`

`#include <vector>`

Classes

- class [IndexOutOfBounds](#)
- class [InvalidPermutation](#)
- class [PermutationMismatch](#)
- class [Permutation](#)

Permutations on n elements.

Functions

- `int * new_seq (int i, int len)`

Return a newly allocated array of length len that counts from i .

6.18.1 Detailed Description

Definition of [Permutation](#) class.

6.18.2 Function Documentation

6.18.2.1 `int* new_seq (int i , int len)`

Return a newly allocated array of length len that counts from i . The returned array should be freed with `delete`.

6.19 props.h File Reference

Include all PROPS header files. `#include "func.h"`
`#include "fourierfunc.h"`

6.19.1 Detailed Description

Include all PROPS header files.

6.20 speedtest.cpp File Reference

A simple way of testing the speed of the FFT. `#include <cstdlib>`
`#include <iostream>`
`#include "props.h"`

Functions

- `int main (int argc, char *argv[])`

6.20.1 Detailed Description

A simple way of testing the speed of the FFT.

6.21 util.cpp File Reference

Utility functions for props.

Functions

- double **fact** (double n)

6.21.1 Detailed Description

Utility functions for props.

6.22 util.h File Reference

Prototypes of utility functions for props.

Defines

- #define **RND(x)** ((x) < 0 ? (int)((x) - 0.5) : (int)((x) + 0.5))

Functions

- double **fact** (double n)

6.22.1 Detailed Description

Prototypes of utility functions for props.
